Weighting is the base two exponent of the *Position* (beginning at zero.)

Lookup is is corresponding *Letter* to *Number* mapping for each *Code*.

Product is the *Weighting* multiplied by the *Lookup*.

Check is the remainder of the *Sum* of the *Products* divided by 11. If the *Check Digit* is 10, then it is mapped to 0 using a modulus operation.

Index is a range 0–35.

Omitted is the quotient of the *Index* minus one, all divided by ten.

Letter is a range 0–Z. It is derived by a lookup in the ASCII table. If the *Index* is less than 10, add 48 to resolve a number. Otherwise, add 55 to resolve a letter.

Number is mapped by adding *Omitted* to the *Index*, thus skipping multiples of 11 including 22 and 33. Note that the dashed lines are where these multiples would have been had they not been omitted.
